MANIPULATING CONTENT OBJECTS TO CONTROL THEIR DISPLAY

[0001] This application is a continuation-in-part application of United States Patent Application Serial No. 09/660,991, entitled "Peer-to-Peer Video Precaching" filed September 13, 2000.

FIELD OF THE INVENTION

[0002] The present invention relates to the field of content precaching in a networked environment; more particularly, the present invention relates to manipulating programs (e.g., scripts) in content objects to control their display.

BACKGROUND OF THE INVENTION

[0003] The World Wide Web ("web") uses the client-server model to communicate information between clients and servers. Web servers are coupled to the Internet and respond to document requests from web clients. Web clients (e.g., web "browsers") are programs that allow a user to simply access web documents located on web servers.

[0004] An example of a client-server system interconnected through the Internet may include a remote server system interconnected through the Internet to a client system. The client system may include conventional components such as a processor, a memory (e.g., RAM), a bus which coupled the processor and memory, a mass storage device (e.g., a magnetic hard disk or an optical storage disk) coupled to the processor and memory through an I/O controller and a network interface, such as a conventional

modem. The server system also may include conventional components such as a processor, memory (e.g., RAM), a bus which coupled the processor and memory, a mass storage device (e.g., a magnetic or optical disk) coupled to the processor and memory through an I/O controller and a network interface, such as a conventional modem.

[0005] To define the addresses of resources on the Internet, Uniform Resource Locator (URL) system are used. A URL is a descriptor that specifically defines a type of Internet resource and its location. To access an initial web document, the user enters the URL for a web document into a web browser program. Then, a request is made by a client system, such as a router or other network device, and is sent out over the network to a web server. Thus, the web browser sends a request to the server that has the web document using the URL. The web server responds to the request and sends the desired content back over the network to the requester. For example, the web server responds to the HyperText Transfer Protocol (HTTP) request by sending the requested object to the client. In many cases, the object is a plain text (ASCII) document containing text (in ASCII) that is written in HyperText Markup Language (HTML); however, the object may be a video clip, movie or other bandwidth intensive content.

[0006] A problem with the Internet is that it has limited bandwidth resources and different points in the Internet may experience network congestion, resulting in poor performance especially for bandwidth-intensive applications. The Internet backbone is often painfully slow. The bandwidth limitation is mainly due to one or more congested links between the web server and the client. Broadband access can help in solving the first mile problem but does not help if the congestion occurs deeper in the network. The

"first-mile" is the first link from the server to the Internet. This can become a bottleneck if the content provider does not provision for sufficient bandwidth on this link or if there is a "flash-flood" of requests to the server.

[0007] High-quality on-demand video over the Internet has been promised for a long time now. Lately, the hype has increased due to the emerging deployment of broadband access technologies like digital subscriber line (DSL), cable modems, and fixed wireless. These technologies promise to bring full motion, TV quality video to consumers and businesses. Unfortunately, early adopters of the technology quickly discovered that they still cannot get video in any reasonable quality over the network. Certainly, broadband access improves the viewing experience - some web sites targeted to broadband connected customers provide movies with slightly higher resolution. However, the video remains as jerky and fuzzy as before, synchronization with the audio is poor, and it requires often tens of seconds of buffering before starting. Nobody would seriously consider this to be an alternative to DVD or analog TV.

[0008] Providing video over the Internet is difficult because video requires huge amounts of bandwidth, even by today's standards. MPEG4-compressed NTSC-quality video, for example, uses an average data rate of 1.2 Mbits/s, with peak rates as high as 3 Mbits/s. MPEG2/DVD quality video consumes 3.7 Mbits/s on the average, with peaks up to 8 Mbits/s.

[0009] Most of today's broadband Internet links, especially those to small to medium-sized businesses (SMBs) typically provide data rates in the 100s of Kbits/s up to 2 Mbits/s. Most residences get asynchronous digital subscriber line (ADSL) technology, which is typically provisioned at approximately 1 Mbits/s for downloads

from the Internet, and 128 Kbits/s for uploads. Often access links are shared among multiple users, which further reduces the bandwidth available to an individual.

[0010] While these data rates are expected to gradually increase in the long term, another phenomenon causing bandwidth shortage will remain: overprovisioning. Typically, Internet Service Providers (ISPs) overprovision their broadband links for economic reasons by a factor of ten. This means that if all their customers would use the service simultaneously, every one of those customers would get only 1/10th of the bandwidth they signed up for. While this scenario might sound unlikely, it is important to note that bandwidth will degrade during peak hours. The problem is better known from cable modems, where customers share a cable segment, but applies to all broadband access technologies.

[0011] The network backbone can also be the bottleneck. Especially backbone peering points are likely to impose low data rates, which slows down end-to-end network speed despite fast last mile technology. Even technology advances such as terabit routers, dense wave division multiplexing (DWDM), and faster transmission equipment will not help significantly if, as expected, Internet traffic continues to keep growing faster than these advances in technology.

[0012] One prior art solution to accommodate the slowness of the Internet backbone is to move content closer to individuals desiring the content. To that end, content may be cached on the carrier edge and requests for such content may be serviced from these caches, instead of the web server servicing the requests.

Distributing content in this manner can require large numbers of cache memories being deployed at the carrier edge and each cache memory stores content from a number of

sites. When a request is made for content from a site that has been stored in one (or more) of the cache memories that is closer (from a network proximity viewpoint) to the requester than the original website, the request is satisfied from the cache. In such a situation, the interactive experience for text and images is improved significantly only if content from the site has been stored in the cache and the individual making the request is close enough to one of the servers supporting such a cache to satisfy requests with the content stored therein. This is referred to as carrier edge caching. One provider of such a service is Akamai. Also, such an arrangement for caching content requires that the content owner and the entity caching the content enter an agreement with respect to the access for that content so that the content can be stored ahead of time. Some of the providers of a carrier edge caching service use dedicated links (e.g., via satellites) to feed web pages and embedded objects to these servers and circumvent the Internet backbone entirely. Providing carrier edge caching for high-resolution video requires a particularly large number of servers to be deployed, since the number of clients each server can handle simultaneously is very small.

[0013] While carrier edge caching takes the load off the backbone and has the potential to significantly improve the end user's experience for text and image-based content, there are two major shortcomings with this approach. First, it requires hardware infrastructure to be deployed on a giant scale. Without servers in all major ISP's point of presence (POPs) and satellite receivers in central offices (COs), caching on the carrier edge does not work effectively. To deploy and maintain this hardware infrastructure is very cost intensive. Second, the last mile access link remains the bottleneck for affordable truly high resolution video for the foreseeable future.

[0014] Thus, high-quality video-on-demand in the strongest sense of the word might be something that will not be available for a while. However, despite all these limitations, a broadband access link of 500 KBits/s can deliver more than 5 GByte of data in 24 hours, which corresponds to 8 hours of NTSC quality video, or 3 hours of DVD quality video - more than most people, especially at work, ever watch.

[0015] Another problem with providing content over the Internet is that a content provider is limited in only being able to display the content in one way and without any insight into what content is already cached at a particular client. This may limit a content provider's ability to control the number and order in which those content objects are displayed as that is under the control of the browser. This is of significance when the content provider only desires to allow display of content to which an individual has subscribed.

BRIEF DESCRIPTION OF THE DRAWINGS

[0019] The present invention will be understood more fully from the detailed description given below and from the accompanying drawings of various embodiments of the invention, which, however, should not be taken to limit the invention to the specific embodiments, but are for explanation and understanding only.

[0020] Figure 1 illustrates a flow diagram of one embodiment of a process for manipulating content objects to control their display.

[0021] Figures 2, 3, 4, and 5 illustrate embodiments of a precaching architecture.

[0022] Figure 6 is an exemplary protocol to facilitate precaching.

[0023] Figure 7 is a block diagram of one embodiment of a computer system.

DETAILED DESCRIPTION

[0024] A method and apparatus for processing content objects prior to their display is described. In one embodiment, the method comprises a client receiving a content object over a network connection, the client, prior to allowing the content object to be dynamically displayed or stored, examining the content object and changing a portion of the content object to reflect information stored locally to the client, and dynamically displaying the content object changed based on the local information at the client.

[0025] The content objects may include web pages, video files, audio files, source code, executable code, programs (e.g., games), archives of one or more of these types of objects, databases, etc. A chapter, for purposes herein, is a set of content objects classified according to content.

[0026] In the following description, numerous details are set forth. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the present invention.

[0027] Some portions of the detailed descriptions that follow are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps

are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical, magnetic, or optical signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

[0028] It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description, discussions utilizing terms such as "processing" or "computing" or "calculating" or "determining" or "displaying" or the like, refer to the action and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (electronic) quantities within the computer system's registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

[0029] The present invention also relates to apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium. A machine-readable medium includes any mechanism for storing or transmitting information in a form readable by a machine (e.g., a computer). For example, a machine-readable medium

includes read only memory ("ROM"); random access memory ("RAM"); magnetic disk storage media; optical storage media; flash memory devices; electrical, optical, acoustical or other form of propagated signals (e.g., carrier waves, infrared signals, digital signals, etc.); etc. Each may be coupled to a computer system bus.

[0030] The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the present invention is not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the invention as described herein.

Overview

[0031] A method and apparatus for processing content objects prior to their display is described. Figure 1 is a flow diagram illustrating one embodiment of a process for manipulating content objects. The process may be performed by processing logic that comprises hardware, software, or a combination of both.

[0032] Referring to Figure 1, the process comprises processing logic (e.g., a client) receiving a content object over a network connection (processing block 101). As described in more detail below, in one embodiment, the content object may come from a content provider or another peer.

[0033] Processing logic (e.g., the client), prior to allowing the content object to be dynamically displayed or stored, examines the content object and changes a portion of the content object to reflect information stored locally to the client (processing block 102). The information may comprise a profile and/or an indication of whether one or more other objects are fully or partially available on the client.

[0034] In one embodiment, an agent (e.g., middleware) running on the client changes the content object after determining that a client has subscribed to this content object or one or more additional objects or knows a certain object or objects, or portions thereof, are in the cache of the client. For example, the agent may change a program (e.g., script) in an HTML document which causes a web page to be displayed in a certain fashion (e.g., only showing content objects already in the client's cache or only those subscribed to). In another example, such a program change may cause the agent to embed an object in another page to display a content object to an individual if that the individual has subscribed to it.

[0035] In one embodiment, an agent on the client changes the content object by replacing at least one string in the content object based on the information stored locally to the client. The string may be a portion of a program (e.g., script). In one embodiment, the content object includes a program that uses the information to indicate how the content object is to be presented or stored at the client and changing the content object comprises modifying the program to change a representation of the content object. The local information upon which a change in the content object is based may be whether an individual is subscribed to one or more other objects and/or whether one or more other objects are stored in a cache of the client.

[0036] Processing logic then dynamically generates a display with and/or of the content object based on the local information at the client (processing block 103). In one embodiment, the content object is displayed using a browser.

One Embodiment of An Architecture for Content Precaching

[0037] The teachings described herein may be utilized in a networked environment that supports content precaching. Figure 2 illustrates one exemplary embodiment of an architecture for content precaching. Referring to Figure 2, one or more content providers (e.g., web servers, video servers, audio servers, etc.) 202 are coupled to the Internet 206 or another networked environment. One or more clients 203 is coupled directly to Internet 206, or indirectly coupled to Internet 206 through a client appliance 205.

[0038] Clients 203 or 204 may comprise a PC, a work station, a network appliance device, a web pad, a wireless phone or other communication device, a set-top box, etc. Client appliance 205 may be implemented on a service gateway (e.g., a router, bridge, switch, other network device) in the LAN or as an end point on the LAN. Clients 203 or client appliance 205 may run software and reside in a LAN or other networked environment. In one embodiment, the precache memory is part of client 203. In another embodiment, the precache memory is part of client appliance 205, or on another client machine that is linked to client 203 by way of a LAN or some other networking subsystem.

[0039] Client 203 or client appliance 205 may be coupled to the Internet by a modem link, a digital subscriber line (DSL), cable modem, (fixed) wireless connection,

fiber, etc. This coupling may be either a direct connection, or indirectly connected through a router, switch, or other similar device.

[0040] One or more clients may be peers. A peer is a "nearby" or local host, such as, for example, a host in the same LAN, a host connected to the same ISP, or any other networked device offering reasonable connectivity (e.g., bandwidth, latency). In Figure 2, any or all of clients 203 or client appliances 205 may be in peer relationships with each other.

[0041] Master controller 201 is coupled to Internet 206 or some other networked environment. In one embodiment, master controller 201 is a server host or cluster of server hosts along with storage (e.g., network-attached storage, database engines), and typically resides in a controlled environment at one or a few locations strategically placed in the Internet to allow for reasonable connectivity.

[0042] In one embodiment, the precaching described herein involves building a user profile, subscribing for update notifications for new content (e.g., objects) based on information in the user profile, downloading the new content, and intercepting user's requests for a web server to transparently return the content to the user. As described in more detail below, a user profile may be built by tracking user access patterns, receiving profile information from another entity, and/or being configured with a profile (or portion thereof) from a user.

[0043] A client may subscribe for an update of new content based on information in the user profile. In one embodiment, periodic checking is performed to obtain an update of new content and includes sending the requests to the controller, which determines if there are any new content objects that correspond to content specified in

the profile. A determination of whether new content exists may be performed by querying a master controller, subscribing with the master controller, and/or crawling the networked environment. Each of these will be described in more detail below.

[0044] In one embodiment, to facilitate the precaching process, the master controller maintains one or more databases of available objects and the locations of the objects. As new content becomes available, the controller searches the database of client profiles to determine the set of clients that will want a copy of the new content. The controller sends a message to each of the clients in the set to instruct them to download the content. The message contains the location from where an object may be downloaded to the client making the request. When the content has already been downloaded by a peer client, the controller may indicate to the client making the request that the peer client has the content and provides an indication to allow the requesting client to download the content from the peer client. Thus, in such a case, there is peer-to-peer precaching.

[0045] In an alternative embodiment, the controller checks for new content, in response to a request by a client, by searching one or more database(s) to determine if the content object has been already downloaded by a client in the system.

[0046] In one embodiment, the clients run on a platform and maintain profiles. A client may be an end point of a network or one or multiple hops away from the end point of a network (e.g., a local area network). By forwarding its profile to the controller and having the controller indicate when to download new content objects, the client is able to obtain and precache content objects prior to web browser or other end user program requests based on profiles. The content objects are downloaded and

stored in a precache memory when the network access link is not being used interactively.

[0047] When a web browser or other end user program makes a request for a content object, the client intercepts the request and checks to determine if it has the content object stored locally. If it is stored locally, then the client obtains the content and sends the content object to the browser or other end-user program using any inter-process communication (IPC) mechanism; in doing so, the object may simply be transferred to another task, process, or thread running on the same machine as the client, or it may travel over a local network (e.g., LAN) to a different machine that is running the browser or end-user program. If the content object is not available locally, then the client retrieves the object, or a low-quality representation of the object, over the wide area network from any server which hosts the content object.

[0048] Thus, each of the client's sends a profile to the master controller (NOC). The master controller gathers information about new objects being published and compares this to the profiles of each client to determine which objects the client's should download. The information of more objects being published may come from content servers. In other words, the master controller indicates to the client(s) when to download specific objects (and when to delete content). The master controller provides this indication in the form of download commands. In other words, after downloading, each client has a collection of cached objects sitting in its cache, which is managed by the master controller.

Discovery of Content

[0049] Master controller 201 can discover content that becomes available at content servers 202. One way in which new content can be discovered is through direct reports 210 coming from content servers 202. Such direct reports 210 could be generated periodically, or in response to an event on server 202 (e.g., new content being placed on the server by the server administrator). Direct reports 210 are usually generated by software running on servers 202.

[0050] Another way in which master controller 201 can discover the availability of content on content servers 202 is by use of a server appliance 207 that is co-located on the server 202's site, or close to it. Server appliance 207 can locally crawl (220) through the content on server 202 frequently to check for the availability of new content. It can then report new changes, or provide a summary of all content on server 202, by sending messages 230 to master controller 201. In this context, the server 202 need not run any special software that can communicate directly with the master controller.

[0051] A third way in which master controller 201 can discover the availability of content on content servers 202 is by directly crawling (240) the content available on content server 202. This crawling operation 240 is similar to the way in which web search engines retrieve files from an Internet web server.

[0052] Figure 3 is an alternative view of Figure 2 illustrating the gathering of profiles. Referring to Figure 3, clients 303 maintains profiles for local users. In one embodiment, the profile is built based on observing user access patterns, and from those access patterns, determining what types of content the end user will want to access in the future. In another embodiment, the profile may be built up or augmented

by information provided directly by the master controller 301 or the end users or both.

A local network administrator may also add to the profile.

[0053] Profiles for one or more clients 304 may also be maintained by a client appliance 305. In this case, it would not be necessary for clients 304 to run special software to collect and report profiles.

[0054] Clients 303 report on the profiles they maintain to master controller 301 using messages 310. Similarly, client appliances 305 report on the profiles they maintain to master controller 301 using messages 320. Messages 310 and 320 can be generated periodically, or in response to some event (e.g., a request from master controller 301).

[0055] Figure 4 is an alternative view of Figure 2 illustrating the initiating of downloads directly from the server. Referring to Figure 4, master controller 401 uses its knowledge of what content is available on content servers (as described in Figure 2), and its knowledge of client profiles for different clients 403 and 404, to initiate downloads of content that will likely be needed in the future at clients 403 and 404. Master controller 401 sends messages 410 to clients 403 and client appliances 405 which contain commands to initiate downloads of content data from locations 402 specified in the messages 410. Clients 403 then send a message 420 to the content server 402 from which the content is to be downloaded. Content servers 402 then respond to these download requests 420 by returning the content data 430 to clients 403. Client appliances 405 retrieve content data from servers 402 in a similar manner.

[0056] Figure 5 is an alternative view of Figure 2 illustrating initiating downloads from peers. Referring to Figure 5, master controller 501 uses its knowledge of which

clients 503 and client appliances 505 have already downloaded specific content objects to initiate downloads of content directly from a peer client. In one embodiment, master controller 501 sends a message 510 to client 503.1 to initiate download of a content object from peer client 503.2. Client 503.1 sends a message 520 to peer client 503.2 to retrieve the specified content. Client 503.2 then acts as a content server by responding to request 520 by sending the specified content data 530 directly back to client 503.1. In another embodiment, master controller 501 can send a command to a client to upload a specified content object to a specified peer client; this is useful when the client sending the content data cannot be directly contacted by the requesting client, perhaps because it resides behind a firewall. Client appliances 505 can get content from peer clients 503 and/or other client appliances in a similar manner.

[0057] In an alternate embodiment of the invention, clients 503 or client appliance 505 may directly query the master controller 501 for new content objects that match their local profiles, and receive from the master controller 501 a list of the new objects that are available, as well as their locations (e.g., content servers 502, peer clients 503, or peer client appliances 505). These queries may occur periodically or in response to some external event (e.g., a request from the master controller). Clients 503 or client appliances 505 can then select a suitable location to directly download the content from. In this embodiment, master controller 501 need not maintain profiles for all the clients, and messages 310 and 320 would be unnecessary.

[0058] In one embodiment, master controller 501 knows four things: 1) the content clients want based on profiles received from clients; 2) the new content that is available; 3) the location of the new content (e.g., servers, carrier edge caches, peers,

etc.); and 4) network information such as, for example, network connectivity (e.g., network topology information, bandwidth, delay, and dynamically changing snapshots of network congestion and/or utilization). Using this information, master controller 501 schedules downloads of new content objects to clients 503 and client appliances 505. Such downloads may take the form of commands such as, for example, "get object from server 1" or may take the form of instructions such as, for example, "instruct client 2 to obtain the object from client 1". The network information and information about which downloads are taking place allow master controller 501 to do provisioning taking into account resource availability.

[0059] In one embodiment, master controller 501 is able to coordinate downloads so that prior to a download of content completing to a particular client, another download of that content may start occurring from that particular client. This kind of pipelining of downloads can significantly reduce the delay before a content object is replicated to a potentially very large number of clients and/or client appliances.

[0060] Clients 503 download content objects from the locations specified in messages 410 or 510 from the master controller. For example, in one embodiment, client 503 may download bandwidth intensive content such as, for example, movies, video, software, images, sound files, etc. Client 503 stores the content locally in one or more precache memories. The precache memory may be part of a client 503 (or is at least accessible by it over a fast link, for example, over a LAN). The content may be downloaded on the end user's premises. In one embodiment, the downloading occurs without excessive interference with any other interactive network traffic.

[0061] A user request may be generated (e.g., from a web browser) to download specific content from the network. Client software running on an end system can observe these requests. Alternately, a client appliance can observe such a request originating from an end system to which it is connected (e.g., through a LAN). Clients or client appliances monitoring these requests can detect when the request is for a content object that is in the local precache memory of the client or client appliance. If such a request is detected, clients or client appliances can intercept the request and satisfy the request by returning the stored (precached) content object from its local precache memory. If the request is for a content object that is not in the precache memory clients or client appliances can forward the request on to their original destination (e.g., content server, carrier-edge cache, etc.). Thus, requests for a specific type of bandwidth intensive content are intercepted. In one embodiment, clients and client appliances are configurable to intercept requests for a certain type of content object.

[0062] Thus, with content cached locally, clients and client appliances detect requests for embedded objects, check their precache memory to determine if the embedded objects are stored locally, and return the object from the precache memory if available. If the content is not available, the request is sent out into the network (e.g., Internet) to an appropriate location where the content or an alternate representation of the content may be found.

Presentation of Objects

[0063] As discussed above, the techniques described herein allow for presenting information in useful ways to a user. In one embodiment, pages are generated dynamically using a local approach. In the local approach, the web page is dynamically generated based on information at the client. In other words, the resulting page that is rendered is based on local information, not content provider (e.g., server) information. The dynamic generation of the content object allows different versions of the object to be displayed based on the information at the client. For example, the page may only be displayed with objects that are already cached. For another example, the pages may be displayed with a particular logo on an object to indicate the object is in the cache or may have cached objects displayed differently (e.g., more prominently) than non-cached objects.

[0064] In the local approach, the content provider supplies the web page. As the web page comes to the client, but before it reaches the browser, an agent running on the client (i.e., middleware) examines the web page and changes the web page to reflect information from the profile and the cached object(s). In one embodiment, the web page contains a program, or script. In one embodiment, the program may comprise Javascript or another scripting language. The program may comprise special macros, which will be replaced by an agent (middleware). These macros may comprise special strings. The agent changes the macros so that when the transformed macros reach the browser and are run by the browser, the browser can render the page based on the local state information, e.g., the contents of a profile, the set of available content objects, etc.

[0065] The agent stored on the client determines whether various objects are subscribed to and whether various objects are in the cache. The agent examines the special set of macros which are embedded as strings and searches the strings and replaces them with special values depending on the profile and the cached objects. For example, the agent may search for a string that indicates whether a content object is in the cache.

String variables

```
<script language = "Javascript">
  if ("Jibe-is-Cached {objA}"=="yes")
    actions to be performed if content object A
    is present in the cache
  else
    actions to be performed if content object A is not in the cache
</script>
```

[0066] The agent searched for strings and replaces the entire string with a value. In the example above, the string "Jibe-Is-Cached {ObjA}" is replaced with "yes" or some other string. In one embodiment, the string is converted into a number. As shown in the script above that is included in a web page, if Jibe-Is-Cached {ObjA} has been replaced with "yes" then certain actions are performed (the browser will see the statement: if ("yes"=="yes"), which evaluates to "true"), while if the variable x has not been replaced with "yes" then certain other actions are performed (the browser will see the statement: if ("Jibe-Is_Cached {objA}"=="yes"), which evaluates to "false").

[0067] In one embodiment, HTML scripting languages are used. In such a case, the agent, if installed on a client, replaces certain patterns in an incoming HTML or with values that can be used in inline scripts (e.g., Javascript) to render the page differently or take some other action based on whether the user is subscribed to a chapter (as

described in more detail below), or other content object, or whether an object is in the user's cache. In one embodiment, the following macros are replaced by the strings specified:

Macro	Value
Jibe-Is-Installed{}	Replaced with the string "yes" if the agent is installed and running
Jibe-Version{}	Replaced with the version number of the agent; valid only if the agent is installed. This may be useful where different actions are to be taken by the agent depending on the version that is installed.
Jibe-Is-Subscribed{cnn.com/sports/baseball} ...the parameter is a chapter name	Replaced with "yes" if the specified chapter is in the user's profile, "no" if it isn't, "unknown" if the page does not belong to the site hosting the chapter (and is therefore not authorized to query the value of this variable). The use of "unknown" may be used in cases where one website (e.g., CNN) asks whether a chapter of another party (e.g., ABC) has been subscribed to. In such cases, the use of "unknown" prevents this information from being released to other such parties.
Jibe-Is-Cached {http://cnn.com/sports/baseball/49ers.avi} ...the parameter is an object name	Replaced with fraction (0-1) of the object that is present in cache, "unknown" if the page does not belong to the site hosting the object (and is therefore not authorized to query the value of this variable)
Jibe-Local-Web-Port{}	Replaced with the port number of the local (client-side) web server that handles confirmations for chapter subscriptions. In one embodiment, the port number is a service identifier to identify different services running on the same machine. The return value can be used by Javascript code to construct a local URL that the browser will be directed to in order to confirm subscription to a chapter. In one embodiment, this function of the content object is only be called if the agent is installed.
Jibe-List-Subscribed-Chapters{}	Replaced with a list of chapters separated by white space.
Jibe-List-Cached-Objects{}	Replaced with a list of cached object names and fraction cached separated by white spaces. e.g., objname1 0.4 objname2 1.0 ...
Jibe-List-Cached-Objects {cnn.com/sports/baseball}	The parameter is used to limit the list to objects belonging to the specified chapter. The number following the object name is the percentage of the content object that is cached.

[0068] In one embodiment, these macros are embedded in a string value in scripts, and if the agent is not present on the client the variables remain unchanged (i.e., equal to their names). Below is an example (using javascript) of how some HTML can be added at a particular location in the document if an object is in cache. The effect of the code below is that a small icon will be displayed at the current location on the page if the object is in cache, and a different small icon will be displayed if it isn't.

```
<script language="JavaScript">
  if ("Jibe-Is-Installed()" == "yes") {
    var is_cached = "Jibe-Is-Cached{http://cnn.com/sports/baseball/49ers.avi}";
    switch (is_cached) {
      case "yes":
        document.write("<img src='http://cnn.com/cached-icon.jpg'>");
        break;
      case "no":
        document.write("<img src='http://cnn.com/uncached-icon.jpg'>");
        break;
      case "unknown":
      default:
        // do nothing
        break;
    }
  }
</script>
```

[0069] The above techniques are used by clients to dynamically generate web pages on the end system (client) (e.g., profile, cached objects). In an alternative embodiment, techniques described herein may be used to allow content providers to dynamically generate their web pages on the server. This is referred to herein as the server approach and is done by providing the content provider with information about the profile and the state of objects that are already in a client's cache.

A Server Approach to Control Display of Content: Sending "Contents of Cache" Information to Providers' Web Servers

[0070] A server may respond to requests from web browsers running on various clients, some of whom may not house the precaching middleware and agent installed. In one embodiment, to distinguish between these clients, the server inserts a special header tag in its responses to these clients. In one embodiment, this tag would be represented as

Jibe: Is-Installed

in the user's responses sent using the HTTP protocol. These special header tags are described to be ignored by clients who do not have the agent installed. Clients that do have it installed, on the other hand, notify the server of its presence by sending the cookie

Cookie: Jibe-version=1.0

on every subsequent request to these servers.

[0071] In the server approach, information is given to the web server which builds the web page (or other content object) dynamically on the server side. In such a case, the client does not have to do anything with respect to the page. In one embodiment, this is done by using cookies, specifically HTTP cookies in one embodiment. When a request is made by a client for a web page, the client sends a cookie as part of the request. The agent on the client inserts the cookies. These cookies may contain all types of information. In one embodiment, information that is sent in the cookies as part of the request includes the contents of the profile and an indication

of the state of the objects corresponding to that content provider that is cached on the client currently.

[0072] In one embodiment, to reduce the amount of information that is sent, a mechanism called a "cookie prefix" is used. A cookie prefix represents a URL prefix. In such a case, information about each object that is associated with the cookie prefix is sent. An example of a cookie prefix is as follows:

`http//cnn.com/baseball`

[0073] In one embodiment, each content object specification contains one or more Cookie-Prefix fields. Whenever the user visits a web page that has a URL whose prefix matches one of the specified Cookie-Prefixes for an object in the cache, the agent adds a special cookie to the HTTP request for that page. An exemplary cookie is given below:

Cookie: Jibe-Object#`http://x.tv/a.mov=0.5`; Jibe-Object# `http://x.tv/b.mov=1.0`;

[0074] The cookie indicates the name of objects that are cached on the client as well as the percentage of how much of each of the named objects are cached. For example, the exemplary cookie given above tells the server that 50% of the a.mov object is cached on the host, and 100% of the b.mov object is cached. Note that these cookies are only sent if the page being accessed falls under the Cookie-Prefix specified in the objects specifications for a.mov and b.mov.

[0075] In other words, the agent inserts cookies in the request indicating that certain objects are in the cache, and these cookies are sent to the server, along with the request. In response, the server dynamically generates a web page based on the information about the client's profile and state of its cache, and sends it to the client.

Subscribing to Chapters

[0076] In one embodiment, content providers can make a user subscribe to a chapter by providing a "subscribe" link on any of their web pages. In one embodiment, when a user clicks on a link, the client goes to the site and the site provides an indication of how to add a chapter to his/her profile. When the user clicks on this link to add a chapter to the profile, instead of going to the remote web site, the user is taken to the middleware agent running on the same machine. This agent returns a page asking the user to confirm whether they want to subscribe to the chapter. The page may result in a pop-up dialog, or it could be a normal web dialog. When the user hits the "confirm" button, the chapter is added to the profile.

[0077] An exemplary HTML construct for this link would have to be preceded by a special HTML comment line. In one embodiment, the HTML snippet is similar to this:

```
<!-- Jibe-Subscribe Chapter-Name="cnn.com/sports/baseball"
      [ Chapter-Title="CNN Baseball" ]
      [ Chapter-Icon="http://cnn.com/images/sports-baseball-icon.jpg" ]
      [ Site-Title="CNN online" ]
      [ Site-Icon="http://cnn.com/cnn-logo.jpg" ]
      [ Cookie-Prefix="http://cnn.com/sports/" ]
      [ Redirect-On-Confirm="http://cnn.com/success.html" ] <
      [ Preferred-Server="host1.cnn.com" ]
      [ Expires="Mon, 2 Feb 2002, 12:23:23 GMT" ]

-->
<a href="http://cnn.com/download-jibe-agent.html">Click here</a> to subscribe to the CNN
Baseball chapter.
```

[0078] Two cases are considered when the agent software is installed and running, and when it isn't. If the agent is not running, then the browser sees the above HTML as is and the information in the HTML comment is ignored. When the user clicks on the link, he will be taken to the URL

<http://www.cnn.com/download-jibe-agent.html>.

[0079] On that page, the user is informed that the user needs to have the agent installed and running in order to subscribe to this chapter. The page has a link from where the user can download the latest version of the agent. This example assumes the content provider has set up a special page from which the user can download the agent. Alternatively, a default download page on a site may be set up to which any content provider can direct their viewers.

[0080] If the agent is already installed and running, it modifies the URL in the subscribe link based on the information in the preceeding HTML comment. In one embodiment, it constructs a URL which points to the local agent and provides all information needed to complete the subscription. In response to the user's selection, the user is automatically taken to a local web page served up by the user's agent, where the user is asked to confirm or deny the subscription (and where the user can choose a weight for the chapter). If the user confirms the subscription by clicking on a "confirm" button on that page, the chapter is added to his profile, and the browser is sent a local web page (also served up by the user's agent) that displays a message confirming to the user that he has successfully subscribed to the chapter.

[0081] In one embodiment, the local web page may also include a Redirect-On-Confirm field. If the Redirect-On-Confirm field is present, then this local confirmation page also contains HTML that automatically redirects the browser to the URL specified by the content provider in the Redirect-On-Confirm field. In case the browser does not implement this redirection (which is done in one embodiment using the meta http-equiv="refresh" mechanism), a link may be included on the local confirmation page which the user can click to be taken to the Redirect-On-Confirm page.

[0082] If the user rejects the chapter subscription request, the chapter is not added to his profile, and the user is taken to another local web page (again, served by the user's agent) which displays an appropriate message.

[0083] In one embodiment, the Cookie-Prefix is used to specify when chapter subscription information should be sent back as a cookie by the agent for a given chapter. Thus, in the above example, if the user is subscribed to the chapter, then whenever that user visits any web page whose prefix is http://cnn.com/sports/ , the web server receives a cookie of the form:

Cookie: Jibe-Chapter#cnn.com/sports/baseball=1;

[0084] If the Cookie-Prefix is missing, chapter subscription information for the chapter will not be sent in cookies.

[0085] Use of cookies is completely optional however, and the content provider is not required to interpret any cookies in order to make the system work for delivering content to their users.

An Exemplary Protocol

[0086] Figure 6 illustrates one embodiment of a protocol for exchanging information between master controller 501 and a client, a server, and a peer. Referring to Figure 6, initially, when the client first boots up, the client registers (601). Registration by the client involves sending information to enable master controller 501 to coordinate the precaching activity.

[0087] In one embodiment, once registration has been completed, all but one of the remaining operations are controlled from master controller 501 (e.g., in response to

a NOC request or message). Thus, master controller 501 sends a request to which the client replies, with the exception of one situation.

[0088] After registration, master controller 501 requests the profile from the client (602). In one embodiment, master controller 501 indicates the size of the profile it is willing to accept or is able to accommodate. Then the client sends the profile to master controller 501 (622). In one embodiment, the profile is a list of links (e.g., 50 to 100 URLs) in order of access frequency, with links that are accessed more often being at the top of the profile. If the profile is larger than the maximum specified by master controller 501, the profile may be made smaller by the client by removing links that have been accessed less frequently (e.g., that are at the bottom of the list of links).

[0089] Similarly, master controller 501 communicates with the web servers (e.g., content providers). A server registers with master controller 501 (603). In response to the registration, master controller 501 requests state information from the server (604). This request may be generated by master controller 501 periodically while the server remains registered. In response to the request, the server sends state information (605). The state information may include a listing of all content objects that are linked through the sites. The list may be limited to only those content objects that are rich media objects or bandwidth intensive objects in terms of downloading. Every time new content is added or removed, the server sends an add message (606) or a remove message (607) to master controller 501 to update the list (e.g., in a database) master controller 501 maintains of the content objects linked through the site.

[0090] In one embodiment, master controller 501 initiates one or more maintenance tests on the client (621). These tests are well-known in the art. For

example, master controller 501 can request traceroutes from this client to some other Internet address or a bandwidth test from the client to a different Internet address. Master controller 501 uses these tests to determine network connectivity and resource availability. With this information, master controller 501 is able to obtain information about the network topology, a network map, etc., as listed above. Note that such information may be provided to master controller 501 directly without the need of testing to discover it. At this point, master controller 501 has information about network topology, information about server size state, and information about clients.

[0091] In one embodiment, master controller 501 may send a reset cache message (609) if a cache checksum doesn't match a previously defined or calculated value.

[0092] Master controller 501 keeps track of where the content is. Specifically, master controller 501 keeps track of a particular content piece (e.g., video clips) and the identity of the servers and/or clients on which it is located. Occasionally, master controller 501 determines that a client is to download some object from a location and at this time, master controller 501 sends an initiate download message (610) to the client that identifies an object and the object's location. In one embodiment, the initiate download message includes the name of the object (e.g., universal resource identifier (URI) and its natural location (e.g., a URL corresponding to its location on the server of its origin, a URL corresponding to some peer client, etc.)).

[0093] In response to the download message, the client initiates the download by sending a get data command to a peer (611). After the peer begins to send the data (623), the client sends a message to master controller 501 indicating that the download has started (612). The download may take a while. Once the download has been

completed, then the client sends a message to master controller 501 indicating that the download has been completed (613). This allows master controller 501 to know which downloads are occurring at any time.

[0094] In case the peer is behind a firewall, then the client cannot connect to the peer directly and download the data from behind the firewall. In that case, master controller 501 sends a message (615) directly to the peer to indicate that the peer is to upload the new content to the client. Master controller 501 also sends a message to the client to expect an upload (614) from some peer. A particular session key or number may be used to correlate uploaded information received by the client from other peer clients with the correct download identified by master controller 501. The peer sends the upload (616). Finally, the client sends a heartbeat message (617) to master controller 501 so that master controller 501 knows that the client is up in and running.

[0095] In one embodiment, the messages are small. Therefore, because almost all requests come from master controller 501, master controller 501 is able to schedule all the downloads to ensure that no single client or network link is being overloaded.

Building User Profiles

[0096] The client creates a profile for an end user that is coupled to the client. The profile may comprise a list of resource locators (e.g., URLs), object type, object size, and a time stamp associated with the URLs to provide information as to when the end user accessed the resource. In one embodiment, the profile comprises URLs and access times, identifying web sites or portions of web sites, and when the user tends to access them.

manually to the profile. For example, if a user checks a set of web sites at a predetermined time during the day, the user can configure the network access gateway to access the web sites prior to that time each day to obtain updated or new content. Such additions to the profile augment the accuracy of the precaching.

[0100] A profile may be developed for a user using a combination of two or more of these profile building methods. Further priorities can be assigned to URLs stored in the precache memory in case of conflicting access times. In one embodiment, user configured URLs have priority over learned URLs (developed from tracking user access patterns) and network administrator configured URLs (e.g., from master controller 501).

[0101] Furthermore, priorities can be given to URLs in case of conflicting access times. For example, in one embodiment, user configured URLs can have priority over "learned" URLs generated from tracking user access patterns and externally configured URLs.

[0102] In one embodiment, only one precaching client is running on a system at any one time. An open application program interface (API) to the profile may be provided to allow third parties to add URLs to user profiles, to schedule downloads, and to use the services provided by the precaching architecture for their applications.

Locating New Content

[0103] In one embodiment, clients may check for new content by subscribing with master controller 501 in the NOC. Clients 503 can subscribe with master controller 501 to get automatic notification when new content becomes available. This is

advantageous on large web sites with millions of clients because it reduces, or even minimizes, time and resources used in crawling.

[0104] Using the information stored in the user profiles, master controller 501 periodically checks for new content. To facilitate this, client 503 may have previously passed updates to its profile, such as shown as arrow 310 in Figure 3. Master controller 510 maintains a list of web sites and their embedded media objects. This list is compiled by using updated information from content providers 502, such as, for example, shown as arrows 210 and 230 in Figure 2, or by crawling web sites from the NOC, such as shown as arrow 240 in Figure 2. The crawling process is similar to the way in which some Internet search engines create indices of web pages.

[0105] In one embodiment, content providers 502 support the system by periodically crawling locally all available web pages on their servers to look for new object content. This local crawl can be implemented by software, hardware or a combination of both.

[0106] The content providers 502 provide a summary of changes to master controller 501. Alternatively, such information may be provided directly to a client. The summary information may comprise the link, time, type and size of each object. The summary may include a list of URLs for those objects. The master controller compares the content in the list with the profile information (e.g., the list maintained by the network access gateway) to determine what content has changed and therefore what content, if any, is to be downloaded. In one embodiment, the result of the local crawl is made available in a special file, namely an update index. Master controller 501

analyzes the update index to find the new download candidates. In one embodiment, content providers 502 manually build an update index.

[0107] Master controller 501 collects and aggregates the summaries. In one embodiment, each content provider 502 sends the summary to master controller 501. In such a case, all the clients need only contact one server to download summary information for groups of participating content servers in the network. In one embodiment, master controller 501 may unicast or multicast the information to one or more clients 503.

[0108] In an embodiment in which clients maintain their own profile, such as described in U.S. Application Serial No. 09/566,068, entitled "Intelligent Content Precaching," filed May 5, 2000, assigned to the corporate assignee of the present invention and incorporated herein by reference, clients 503 directly crawl a web site and search for new content objects. Clients 503 perform a crawl operation by periodically checking web servers indicated in the profile for new or updated content objects that it believes end users or other local devices will be accessing in the near future. In one embodiment, in such a case, a client begins with a URL stored in the profile and follows links into web pages down to a configurable level.

[0109] In one embodiment, the controller obtains the first page from the server and determines if any bandwidth intensive objects are present. In one embodiment, a bandwidth intensive object may be identified by its size. If bandwidth intensive, embedded objects exist, the controller determines if new versions are available and downloads them. When new content objects have been identified, the controller indicates to the client to download only the bandwidth intensive (e.g., large), new

content objects (as they become available). The content objects obtained as a result of crawling are stored locally. In one embodiment, the precache memory storing such objects also stores their URLs, data type, size, the time when the data was acquired and the actual data itself. This process is transparent to the network and no change is needed to the content servers or the network to operate the precaching client.

[0110] In an alternative embodiment, each new and/or updated content object is downloaded independent of size (after determining if the content object is a new version).

[0111] Some or all of these crawling techniques may be used in the same networked environment. For example, client 503 may crawl one or more sites to determine if any of the content objects have changed, while receiving information from master controller 501 or web servers employing a mechanism to crawl their sites to identify updated or new content and while caches in the network or content servers provide updated and new content to the client 503.

Downloading

[0112] Master controller 501 in the NOC maintains a database of available objects and their physical location. When a new object is available for downloading to client 503, master controller 501 determines the most suitable location from which client 503 may download the object. In one embodiment, master controller 501 does this by analyzing the database and the client's Internet protocol (IP) address, and relating this to network topology, map, and connectivity information known to it. A scheduler in the NOC returns a download trigger to client 503. The trigger provides information to

enable client 503 to download the object. This trigger information, or pointer, may comprise a location and an object name (e.g., URL).

[0113] A requested object can be downloaded from a variety of sources, e.g. a peer, a carrier edge cache, or the original server. In Figure 5, arrow 530 represents a download from a peer. Management controller 501 determines the most suitable host based on parameters. In one embodiment, these parameters include peer-to-peer hop count and bandwidth.

[0114] If no suitable peer is available (e.g., if the request is the first request for an object or if suitable peers are too far away), the object can also be downloaded from a server installed on the carrier edge if the content provider supports carrier edge caching. If there is no suitable peer and no cache can be found, the object is downloaded from the original content provider server 502. Client 503 downloads the object in the background without excessively interfering with interactive traffic, regardless of the location from which it downloads.

Intercept

[0115] In one embodiment, client 503 transparently analyzes the web pages downloaded by the end users and rewrites embedded URLs in web pages to point to the locally precached object instead of the original object. In rewriting URLs, specific marks (e.g. a different link color or an additional icon) for objects available in the precache can be added. When the user finally selects (e.g., clicks) on a link, the browser automatically loads the object from the precache instead of the content provider server.

[0116] Client 503 may intercept requests for content objects in different ways. For example, in one embodiment, client 503 monitors requests and when there is a request for a content object stored by (or for access by) client 503, it takes the request and responds to the request as if it were originally addressed for client 503. Thus, an end user generating the request receives the content object as if it had received the content from the original server hosting the content. This is one example of an implicit way to translate an access for a content object to a locally cached object. The interception of requests may be done explicitly where an end system is aware of the new location of the object (e.g., through DNS lookup). In one embodiment, client 503 checks for certain types of requests, which correspond to content available in the precache memory (e.g., all *.mov files). If such a request is detected, the client searches the precache memory for the requested URL.

Applications

[0118] Mapped content allows customers to offer dense content dedicated to precache-enabled users. In one embodiment, this is implemented by offering a separate high resolution file of a video clip which is not linked into any web page, but is available to the master controller when it checks a target web site for new content.

When the user clicks on a video icon on a web page, the transparent precache technology delivers the high resolution version instead of the potentially low resolution version.

[0119] In aggregated access statistics, access statistics and user profile statistics are provided to content providers and distributors. For example, individual user access profiles on the customer premises are retained, with the statistics being reported. By only reporting the aggregated statistics, privacy concerns are avoided.

[0120] Besides enhancing traditional web sites with high-quality video, the precaching technique can be applied in other areas, such as advertising, and DVD on demand. Running decent quality video advertising over the Internet has not been possible so far. A broadband connection can barely deliver a single low-quality video stream, and consumers would certainly not want video ads to eat up their interactive bandwidth. Thus, advertisers are currently limited to using "banner ads," which are mostly implemented as blinking images (animated GIFs). With precaching, advertisements can be downloaded while the link is not used otherwise. Thus, full motion ads can be downloaded in the background, and embedded in web pages, without exhausting the interactive bandwidth. The peer-to-peer video precaching technique helps advertisers to succeed in their hunt for eye balls. In addition, the precaching technique allows the advertisers and content providers to retain their ability to keep track of the number of "hits" of the embedded ads.

[0121] The precaching technique also makes online distribution of DVD video feasible. The hassle with late fees, midnight video store runs and rewinding charges would be avoided using an online renting model. MPEG2 video, the coding standard

used on DVDs, requires an average bandwidth of 3.7 Mbits/sec. The average length of a DVD movie is two hours. An average movie needs approximately 3.5 Gbytes of disk space. Over a 500 kbits/sec Internet connection, three hours of DVD-quality movie can be downloaded in 24 hours. If the connection is twice as fast (e.g., 1 Mbit/sec), three full DVD movies can be delivered over the Internet in a day.

[0122] Thus, a technique of personalized content delivery using peer-to-peer precaching has been described. In particular, this technique saves content providers bandwidth on their server farms and carrier edge caches. It also improves the interactive experience of a large number of web sites. While the previous discussion focuses on clients running on end system PCs, the technique can be implemented to run in access gateways, home gateways, set-top boxes, etc.

An Exemplary Computer System

[0123] Figure 7 is a block diagram of an exemplary computer system (e.g., PC, workstation, etc.) that may be used to provide one or more of the operations described herein. Referring to Figure 7, computer system 700 may comprise an exemplary client 503 or server 502 computer system. Computer system 700 comprises a communication mechanism or bus 711 for communicating information, and a processor 712 coupled with bus 711 for processing information. Processor 712 includes a microprocessor, but is not limited to a microprocessor, such as, for example, Pentium™, PowerPC™, Alpha™, etc.

[0124] System 700 further comprises a random access memory (RAM), or other dynamic storage device 704 (referred to as main memory) coupled to bus 711 for storing

information and instructions to be executed by processor 712. Main memory 704 also may be used for storing temporary variables or other intermediate information during execution of instructions by processor 712.

[0125] Computer system 700 also comprises a read only memory (ROM) and/or other static storage device 706 coupled to bus 711 for storing static information and instructions for processor 712, and a data storage device 707, such as a magnetic disk or optical disk and its corresponding disk drive. Data storage device 707 is coupled to bus 711 for storing information and instructions.

[0126] Computer system 700 may further be coupled to a display device 721, such as a cathode ray tube (CRT) or liquid crystal display (LCD), coupled to bus 711 for displaying information to a computer user. An alphanumeric input device 722, including alphanumeric and other keys, may also be coupled to bus 711 for communicating information and command selections to processor 712. An additional user input device is cursor control 723, such as a mouse, trackball, trackpad, stylus, or cursor direction keys, coupled to bus 711 for communicating direction information and command selections to processor 712, and for controlling cursor movement on display 721.

[0127] Another device that may be coupled to bus 711 is hard copy device 724, which may be used for printing instructions, data, or other information on a medium such as paper, film, or similar types of media. Furthermore, a sound recording and playback device, such as a speaker and/or microphone may optionally be coupled to bus 711 for audio interfacing with computer system 700. Another device that may be

coupled to bus 711 is a wired/wireless communication capability 725 to communication to a phone or handheld palm device.

[0128] Note that any or all of the components of system 700 and associated hardware may be used in the present invention. However, it can be appreciated that other configurations of the computer system may include some or all of the devices.

[0129] Whereas many alterations and modifications of the present invention will no doubt become apparent to a person of ordinary skill in the art after having read the foregoing description, it is to be understood that any particular embodiment shown and described by way of illustration is in no way intended to be considered limiting.

Therefore, references to details of various embodiments are not intended to limit the scope of the claims which in themselves recite only those features regarded as essential to the invention.
